

# COMP 6721 Applied Artificial Intelligence (Fall 2023)

## Worksheet #8: Knowledge Graphs & Intelligent Agents, Part II

**N-Triples.** Quick refresher: Using the N-Triples serialization format, write an RDF triple describing Concordia's *website* as recorded in [wikidata.org](https://www.wikidata.org/wiki/Q108862):

**Your first Vocabulary.** Define the fact that *Student* is a **class** (as opposed to an instance, like *Jane*). Use the following prefix definitions and define *Student* as part of the **ex** namespace (**ex:Student**):

```
@prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#> .
@prefix rdfs: <http://www.w3.org/2000/01/rdf-schema#> .
@prefix xsd: <http://www.w3.org/2001/XMLSchema#> .
@prefix ex: <http://example.org/> .
```

Add the triple: .....

**Creating Instances.** Now add another triple stating that Jane (**ex:jane#me**) is of type **ex:Student**:

**Subclasses.** For now at least, every *Student* is a *Person* (sorry, robots!). Define this fact as a triple (use **foaf:Person** for the namespace):

Note: use the same **ex:** namespace for the new subclass as before for *Student*.

**Properties.** We now define a *property*, **studiesAt**, so that we can indicate at which university a student is studying. Write the triple defining **studiesAt** as a *property* (use the **ex:** namespace as before):

(Note: properties should also have labels & comments, but we omit this here for brevity.)

Construct	Syntactic form	Description
<a href="#">Class</a> (a class)	<b>C</b> <b>rdf:type</b> <b>rdfs:Class</b>	<b>C</b> (a resource) is an RDF class
<a href="#">Property</a> (a class)	<b>P</b> <b>rdf:type</b> <b>rdfs:Property</b>	<b>P</b> (a resource) is an RDF property
<a href="#">type</a> (a property)	<b>I</b> <b>rdf:type</b> <b>C</b>	<b>I</b> (a resource) is an instance of <b>C</b> (a class)
<a href="#">subClassOf</a> (a property)	<b>C1</b> <b>rdfs:subClassOf</b> <b>C2</b>	<b>C1</b> (a class) is a subclass of <b>C2</b> (a class)
<a href="#">subPropertyOf</a> (a property)	<b>P1</b> <b>rdfs:subPropertyOf</b> <b>P2</b>	<b>P1</b> (a property) is a sub-property of <b>P2</b> (a property)
<a href="#">domain</a> (a property)	<b>P</b> <b>rdfs:domain</b> <b>C</b>	domain of <b>P</b> (a property) is <b>C</b> (a class)
<a href="#">range</a> (a property)	<b>P</b> <b>rdfs:range</b> <b>C</b>	range of <b>P</b> (a property) is <b>C</b> (a class)

**Are we there yet?** Ok, let's look at these three triples (written in pseudocode for brevity):

```
<FG-C070> <teaches> <COMP6721> .
<professor> <is a> <slide> .
<student> <handed in by> <assignment> .
```

Are these *syntactically* legal triples? (Spoiler alert: yes, we could write each of them using perfectly fine RDF URIs.) So what exactly is wrong here? (Discuss with your worksheet team partner!)

**Domain & Range.** We now have to add *domain and range restrictions* for our property to avoid problems like the ones shown above. For the *domain* of our `studiesAt` property, we only permit `ex:Student` resources and for the *range*, we only admit `ex:University` resources. Write the two triples:

1. ....
2. ....

**FOAF.** A widely used vocabulary for describing people and their (social) networks is *Friend-of-a-Friend* (FOAF), which you've seen before:

```
PREFIX foaf: <http://xmlns.com/foaf/0.1/>
```

1. Assume Joe has a photo of him published under `http://facebook.me/joe.png` (not a real URL). How can you add this information to the knowledge graph using FOAF (hint: look up the vocabulary using the prefix URL above):

.....

2. Again using FOAF, model that *Jane* is 22 years old:

.....

**Linked Data.** How is Concordia University in the DBpedia knowledge graph *linked* to Wikidata? Find the *property* and *object* for:<sup>1</sup>

```
<http://dbpedia.org/resource/Concordia_University> .....
```

**SPARQL.** Your first SPARQL query: What can you find in Wikidata with (use the public SPARQL query interface at <https://query.wikidata.org/>):

```
SELECT ?book ?bookLabel
WHERE
{
  ?book wdt:P50 wd:Q35610 .
  ?book rdfs:label ?bookLabel
}
```

**Your own AI Agent.** Consider the output of a commercial AI, for example the *Google Assistant*, when you ask a question like “*What is Concordia University?*”: You’ll typically see a definition as part of the answer that often comes from Wikipedia (“*Concordia University, commonly referred to as Concordia, is a public comprehensive research university located in Montreal, Quebec, Canada...*”). Write a SPARQL query that retrieves this information from DBpedia, using its public query interface at <https://dbpedia.org/sparql/>. Hint: use the `rdfs:comment` field (`dbr:` is a pre-defined prefix for `http://dbpedia.org/resource/`):

```
SELECT ?description
WHERE {

  dbr:Concordia_University . . . . .

}
```

<sup>1</sup>Note: similar to Wikidata’s `/resource` to `/wiki` redirect, DBpedia will display a human-readable HTML page for a `/resource` under the `/page` path, whereas programs would be redirected to the `/data` path for the raw RDF data.
